φ = (when → then)

rule_to_z3 gives this in both columns — it describes the CONTENT, so degeneracy checking applies to a permission too

obligation — O(then | when)

`violation_condition = when ∧ ¬then`

“We recommend anticoagulant prophylaxis.”

A patient who meets when without then is a real deviation, and the three-valued verdict applies in full.

GRADE-conditional stays here: “we suggest X” is weak EVIDENCE, not an optional action.

permission — P(then | when)

`violation_condition = FALSE, unconditionally`

“Epidural analgesia may be considered.”

There is no patient, and no completion of the unknowns, for which this yields MUST-violate. The verdicts are OPTION-taken, not-taken, available, not-applicable — none is an accusation.

Measured: 15% of real recommendations are permissive.

`The fallback only ever moves obligation → permission, never the reverse.`

Guessing permission wrongly silences an alert, which is recoverable. Guessing obligation wrongly accuses a clinician, which is not.
